# **Information Retrieval and Data Mining**

Porject 1 2020-2021

#### Team 2

### Karypidis Stathis Github

## Anagnostou Pantazis Github

**Abstract:** In this project we conduct an experiment on the basics of information retrieval. The project was based on the Lemur Project or Indri Search Engine. More specifically, we have 4 collections of texts (fbis, fr94, ft, latimes) and 150 information needs/topics which are tested on two different retrieval models. The first one is the default model that Indri has and its results will be our baseline results. On the other model we use query expansion with Relevance Feedback of terms of the collections or terms from a thesaurus. The version of the Lemur Porject used is 5.11 on Ubuntu 16.04 and the evaluation tool used in trec eval 9.07.

The code of this project can be found on github: <a href="https://github.com/pantanag/IR-DM-Exercise-2020-21-Team-2">https://github.com/pantanag/IR-DM-Exercise-2020-21-Team-2</a>

#### Part A

In the first part of this project we use the default retrieval model of Indri. After the setup of Indri is complete, we use the command to build our index of terms of our collections (default tokenizer and Krovetz stemmer) after we have modified the parameter file "IndriBuildIndex.parameter.file.Example" to our needs. More specifically, we add the paths to our collections and the path that our index is going to be stored.

```
1
    <parameters>
 2
     <corpus>
 3
       <path>/home/stathis/Downloads/IR-2019-2020-Project-1/ft</path>
 4
       <class>trectext</class>
 5
     </corpus>
 6
     <corpus>
 7
       <path>/home/stathis/Downloads/IR-2019-2020-Project-1/fr94</path>
       <class>trectext</class>
 8
 9

     <storeDocs>true</storeDocs>
21
     <stemmer><name>Krovetz</name></stemmer>
22
    </parameters>
```

Next we use the command mentioned before IndriBuildIndex IndriBuildIndex.parameter.file.Example to build our index. With the command dumpindex /path/to/index v we can see our index too. The next step is the creation of a joint file containing all the qrels files (relevant judgments) with the use of the command cat qrels.301-350.trec6.adhoc qrels.351-400.trec7.adhoc qrels.401-450.trec8.adhoc > qrels.301-450.trec.adhoc and the creation of a file containing all the information needs (topics) with the corresponding command cat topics.301-350.trec6 topics.351-400.trec7 topics.401-450.trec8 > topics.trec. If we are given the above files we can skip to next part which is the creation of the three (3) queries files. After having read the queries file with only the titles (was given as an example) we proceed to remove any punctuation and handle any specific characters so that our 3 files are in the best format possible (and that Indri can understand them).

Our results were the below:

|                    |     |        |  | 🕲 🖨 📵 eval_results_titles-desc.txt (~/Downloads/trec_eval-9.0.7) - gedit |                      |     | 😮 🖨 📵 eval_results_titles-desc-narr.txt (~/Downloads/trec_eval-9.0.7) - ged |  |                 |      |     |        |  |

|                    |     |        |  |  |                      |     |   |  |                 |      |     |        |  |

The metrics we are interested in are the below:

| Metric                 | title  | title+desc | title+desc+narr |  |  |
|------------------------|--------|------------|-----------------|--|--|
| Mean Average Precicion | 22.17% | 22.95%     | 22.4%           |  |  |
| R-Precision            | 26.91% | 27.67%     | 27.01%          |  |  |
| Precision@10           | 42.73% | 43.67%     | 43.33%          |  |  |

While observing the results we can see that our metrics dont vary so much across the three fields. Obviously the queries containing both the title and the desc give the best results (based on the metrics above). While adding the desc clearly boosts our results, adding the narr field too doesnt improve our search. This indicates that adding the desc field provides us with extra information but adding the narr field too comes to surplus. Let's look at the arithmetic mean of the Average Precision or MAP (mean of AP at the different values of Recall or area below the curve Precision - Recall). As we can see its between 22-23% for the first 3 cases. Then we examine the R-precision or the percentage  $\frac{r}{R}$  where  $\mathbf{r}$  is the number of our relevant results of a query until the first  $\mathbf{R}$  texts where  $\mathbf{R}$  is the number of relevant texts for the query. This metric has also not so good results being between 26-27%. Finally, regarding the Precision@10 we notice that it greatly higher than our previous two metrics. The results of the MAP and R-precision indicate that our retrieval quality isn't so good while the results of the Precision@10 indicate that even for the first 10 texts, 4 or 5 max texts are relevant with our search. In the next part we examine the query expansion with Relevance Feedback.

#### Part B

As mentioned before, in this part of the project, we use query expansion. Moreover, we acquire the 20-most frequent terms on the 15 most relevant texts of our query (based on the results of the Relevance Feedback). Apart from that we use a thesaurus to produce synonyms of those terms and add them to our improved query too. To do this, we must first examine our results to get the 15 most relevant texts/titles(files: "results-titles.trec" and "results-titles-desc.trec"). The function responsible for that is the following:

```
def get_top15(filename):
 1
 2
        #Open file with results
 3
        f = open(filename+".trec","r")
        lines = f.readlines()
 4
 5
        previous = ""
 6
        num_queries = []
 7
        final = \{\}
 8
        counter = 0
 9
        #Read every line and check for a new number query
        for i in range(0,len(lines)):
10
            line = lines[i]
11
12
            line_values = line.split()
13
            if(line_values[0] != previous):
14
                 num_queries.append(line_values[0])
                 previous = line_values[0]
15
                 #New query found so start keeping best 15
16
17
                 start = True
18
             if(start):
19
                temp = []
20
                 for k in range(0,15):
21
                     temp.append(lines[i].split()[2])
22
                     i = i+1
23
                 start = False
24
                 final[num_queries[counter]] = temp
25
                 counter = counter +1
26
        return final
```

After we have found the 15 most relevant titles, we must find the corpus its title belongs to. To do this we built a lexicon (stored as a json file) so that we have we have a correspondence between the texts (titles) and the corpus they belong to. The file containing them is the **paths.json** and its necessary for the **partB.py** to run (must be in the same folder). In case we don't have the lexicon then the function searches all the collections to find the right one and then searches the right text (the use of the lexicon is highly recommended becasue it's a lot faster).

After we have found the right collection the article belongs to all that remains is for us to open it and extract the text. Once we have extracted the text , we tokenize it and we use the library **Counter** to keep track of the frequency of its term in the text.

```
#Function to retrieve text from the file obtained before
 1
 2
    def retrieve_text(filename,title):
        text = ""
 3
        #Pattern for html and etc tags
 4
 5
        cleanTags = re.compile('<.*?>')
 6
        #Open and read file
 7
        with codecs.open(filename, "r", encoding="latin-1") as data:
 8
            lines = data.readlines()
 9
            for i in range(0,len(lines)):
                line = lines[i]
10
                #Find the right section of our file and gather only the <TEXT> part
11
                if title in line:
12
```

```
13
                    i = i + 1
                    while("<TEXT>" not in lines[i]):
14
15
                         i=i+1
16
                     i = i+1
                     while("</TEXT>" not in lines[i]):
17
18
                         #Remove html tags and dont add empty or newlines
19
                         tempLine = re.sub(cleanTags,"",lines[i])
                         if tempLine not in ["","\n"]:
20
21
                             text = text + tempLine
                         i=i+1
22
23
        #Remove punctuation
24
        out = text.translate(text.maketrans('','',string.punctuation))
25
        return out
26
    #Create dictionary of tokenized words and their frequency
27
    def make_dict(text):
28
        ks = krovetz.PyKrovetzStemmer()
        #Use nltk tokenizer to get every word in the text
29
        lista = nltk.word_tokenize(text)
30
31
        lista = [ks.stem(word) for word in lista]
32
        counter = Counter(lista)
33
        #Create stopwords array to dismiss them later
34
        stopwords = nltk.corpus.stopwords.words('english')
35
        stopwords.extend(list(string.ascii_lowercase))
36
        stopwords.extend([word.capitalize() for word in stopwords])
37
        pops = set(stopwords).intersection(counter.keys())
38
        for i in pops:
39
            counter.pop(i)
        most_common = sorted(counter.items(),key = lambda pair: (-pair[1],pair[0]))
40
41
        #Return only first 50 words
42
        return most_common[0:50]
```

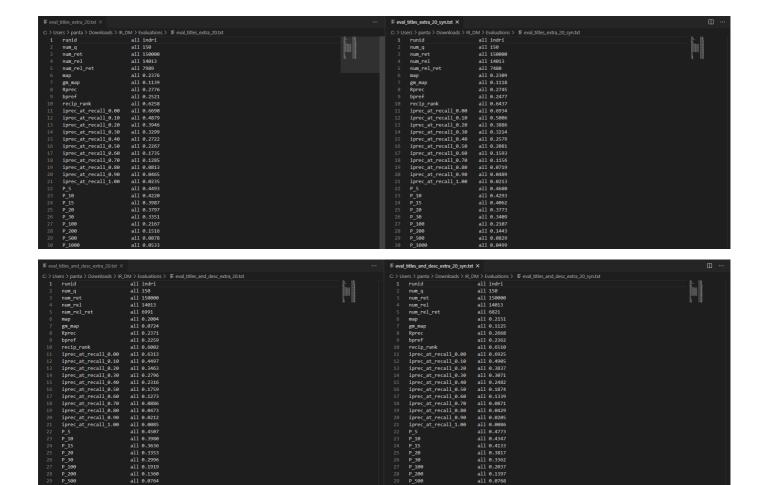

As we can see in the above code our function returns the 50 (not 20) most frequent terms in the 15 most relevant texts that were retrieved. The reason behind this is that we want to avoid cases of double-terms when we proceed to query expansion. Finally, all that's left to do is the query expansion while avoiding the double effect mentioned before and cases of vehicle-vehicles (by using **Krobetz Stemmer**). Our improved queries are then built and ready to be tested. The function responsible for all those things mentioned is the below:

```
1
    def create_improved_queries(json_file,originalQueries,output,weight):
 2
        #Data extraction from json file
 3
        f = open(json_file+".json",'r')
        data = json.load(f)
 4
 5
        f.close()
 6
        keys = sorted(data.keys())
 7
        currPath = os.getcwd()
 8
        if not os.path.exists("Improved Queries"):
 9
            os.mkdir("Improved Queries")
        os.chdir(currPath + "/Improved Queries")
10
        #Create dictionary for current (old) queries
11
12
        count = 301
13
        queries = {}
        originalQueries = remove_pun(originalQueries)
14
15
        for q in originalQueries:
16
            queries[str(count)] = q
17
            count+=1
        #Create improved queries
18
19
        improvedQueries = []
20
        for key in keys:
            temp = ""
21
22
            items = data[key]
```

```
#Count to keep track of number of iterations (we want top 20 only)
23
24
            tempCount = 0
            for item in items:
25
26
                #Check for duplicates
                if item[0].lower() not in queries[key].lower() and tempCount < 20:
27
                     temp = temp + " " + item[0]
28
29
                     tempCount +=1
30
            #Build new improved query
31
            improvedQueries.append(temp)
        write_queries(originalQueries,output+"extra-20-queries",improvedQueries,weight)
32
33
        queries_extra = combine_texts(originalQueries,improvedQueries)
34
        tempCount = 0
        #Create synonyms queries
35
36
        synQueries =[]
37
        ks = krovetz.PyKrovetzStemmer()
        for query in queries_extra:

After we have created the improved queries, we use the indri search engine to rerun our information need and then compare our results with **trec\_eval**. The below images represent the evaluation for each method in the corresponding field. The first image shows the evaluation of the improved queries (**left**: extra terms, **right**: extra terms and synonyms) based only on the "titles-only" queries while on the second image the improved queries are based on the "titles-and-desc" queries (with the phrase based on we mean that those were the results that were used for the relevance feedback).

\*extra: most frequent

In the following matrix we see the metrics we are interested in:

| Metric                    | titles +<br>extra20 | titles + extra20<br>+ syn | titles + desc +<br>extra20 | titles + desc + extra20<br>+ syn |  |  |
|---------------------------|---------------------|---------------------------|----------------------------|----------------------------------|--|--|
| Mean Average<br>Precicion | 23.76 %             | 23.09 %                   | 20.04 %                    | 21.51 %                          |  |  |
| R-Precision               | 27.76 %             | 27.45 %                   | 23.71 %                    | 26.68 %                          |  |  |
| Precision@10              | 42.2 %              | 42.93 %                   | 39.8 %                     | 43.47 %                          |  |  |

Based on the results above we can come to some conclusions. The extra terms (most frequent ones) and the synonyms applied to the "titles-only" original queries improved by a small percentage the <u>MAP</u> while the "titles-and-desc" decreased it by a lot. This can be explained by the length of our query which in the latter case is extremely large. In the <u>R-Precision</u> we observe the same things as the <u>MAP</u>. Moreover, on the "titles-only" with teh extra terms we see our best score. Finally, for the <u>Precision@10</u> (which was explained in the part A of this project), we once again see simillar percentages (between 40-43.5). As we can understand our improved queries, which used for the Relevance Feedback only the titles (and not the desc too), improved our <u>MAP</u> and <u>R-Precision</u> percentages and kept <u>Precision@10</u> to the same levels (realistically we had a slight drop). On the other hand by using both the titles and the desc for the Relevance Feedback we dropped our metrics.
